

On the number of elliptic curves with prescribed isogeny or torsion group over number fields of prime degree

Filip Najman

Abstract

Let p be a prime and K a number field of degree p . We count the number of elliptic curves, up to $\overline{K}$ -isomorphism, having a prescribed property, where this property is either that the curve contains a fixed torsion group as a subgroup, or that it has an isogeny of prescribed degree. We also study the following question: for a given n such that $|Y_0(n)(\mathbb{Q})| > 0$, does every elliptic curve over K with an n -isogeny have a quadratic twist with torsion $\mathbb{Z}/n\mathbb{Z}$ as a subgroup? We prove that this is true only for the cases $n = 2, 3, 4, 6$ and for the pairs $(n, K) = (11, \mathbb{Q}(\zeta_{11})^+)$ and $(n, K) = (14, \mathbb{Q}(\zeta_7)^+)$.

Mathematics Subject Classification (2010) 11G05, 11G18, 14H52

1 Introduction

Our goal is to study the number of elliptic curves over number fields of prime degree $K/\mathbb{Q}$, up to $\overline{K}$ -isomorphism, having a prescribed property. This property will be one of the following:

- 1) The curve has a fixed torsion group T as a subgroup.
- 2) The curve has an n -isogeny, for some prescribed n .

Our methods will actually also solve the first problem for number fields of degree d , where d is not divisible by any of 2, 3 or 5.

It is clear that, when counting the number of elliptic curves with an n -isogeny, one has to count up to $\overline{K}$ -isomorphism, since if E/K has an n -isogeny, then so does every quadratic twist of E (in other words, the modular curve $Y_0(n)$ classifying n -isogenies is a coarse moduli space).

On the other hand, it is not clear whether it is better to count elliptic curves with prescribed torsion up to K -isomorphism or $\overline{K}$ -isomorphism. Since we will mostly be concerned with the finiteness of the number of curves with given torsion, and taking into account that one can deduce from [18, Lemma 5.5] that there will be finitely many elliptic curves over K containing T up to $\overline{K}$ -isomorphism if and only if there are finitely many such curves up to K -isomorphism, we see that the choice of the isomorphism does not really matter.

Thus, for simplicity's sake, we will always count elliptic curves up to $\overline{K}$ -isomorphism, and we will do so, usually without mention, throughout the paper.

The number of curves will naturally depend on the prescribed property. Denote by $Y_1(m, n)$ the affine modular curve whose K -rational points classify isomorphism classes of the triples (E, P_m, P_n) , where E is an elliptic curve (over K) and P_m and P_n are torsion points (over K) which generate a subgroup isomorphic to $\mathbb{Z}/m\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}$. For simplicity, we write $Y_1(n)$ instead of $Y_1(1, n)$. Let $X_1(m, n)$ be the compactification of the curve $Y_1(m, n)$ obtained by adjoining its cusps. Denote by $Y_0(n)$ the affine curve whose K -rational points classify isomorphism classes of pairs (E, C) , where E/K is an elliptic curve and C is a cyclic ($\text{Gal}(\overline{K}/K)$ -invariant) subgroup of E . Let $X_0(n)$ be the compactification of $Y_0(n)$.

The key value that will determine whether the number of elliptic curves with a prescribed property is finite or infinite is the genus of the appropriate modular curve X , where $X = X_0(n)$ or $X_1(m, n)$. If X is a genus 0 curve, then $X(K)$ has either none or infinitely many points, thus implying that there are none or infinitely many curves with the given property. Note that one can determine in finite time, by the Hasse principle, whether there are any points in $X(K)$.

In particular, for $X = X_1(m, n)$ of genus 0 and $m > 2$, that is for $(m, n) = (3, 3), (3, 6), (4, 4)$, or $(5, 5)$, the number of elliptic curves over a number field K with a subgroup isomorphic to $\mathbb{Z}/m\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}$ is infinite if and only if K contains ζ_m , an m -th primitive root of unity, and zero otherwise. One direction follows from the Weil pairing, and the other from the fact that the curve $X_1(m, n)$ has a $\mathbb{Q}(\zeta_m)$ -rational point (and hence infinitely many) for all of the listed pairs.

On the other hand, if X is of genus ≥ 2 , then by Faltings' theorem [5], $X(K)$ has only finitely many points. Thus, we see that we are left only with the genus 1 case.

In Section 2 we count the number of curves containing a prescribed torsion group. We obtain that for a number field K of prime degree $p > 5$,

if $X_1(m, n)$ is of genus 1, then there are either none or infinitely many elliptic curves containing $\mathbb{Z}/m\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}$ as a subgroup. We actually prove a stronger statement (see Theorem 1).

If K is of degree 5, then there are 3 elliptic curves with 11-torsion over $\mathbb{Q}(\zeta_{11})^+$ and either none or infinitely many elliptic curves over K containing $\mathbb{Z}/m\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}$ as a subgroup for all other triples (K, m, n) such that $X_1(m, n)$ is of genus 1.

Combining this with the results of [8] and [19], we solve the problem for number fields of prime degree completely.

In Section 3 we study the number of curves having an n -isogeny, for a prescribed n .

In Section 4 we examine the relationship between the number of elliptic curves with an n -isogeny and n -torsion. More specifically, we can wonder whether, over a number field K of prime degree, every elliptic curve with an n -isogeny has a quadratic twist with a point of order n . We prove that this is true only in the trivial cases $n = 2, 3, 4$ or 6 (for any K) and for the pairs $(n, K) = (11, \mathbb{Q}(\zeta_{11})^+)$ and $(n, K) = (14, \mathbb{Q}(\zeta_7)^+)$.

2 Number of elliptic curves with prescribed torsion

As stated in the introduction, we need to study the modular curves $X_1(m, n)$ of genus 1. One can see in [6, Theorem 2.6, Proposition 2.7] that $X_1(m, n)$ is of genus 1 only for $(m, n) = (1, 11), (1, 14), (1, 15), (2, 10), (2, 12), (3, 9), (4, 8)$ or $(6, 6)$. Note that if K is a field of odd degree, the cases (m, n) , where $m|n$ and $m > 2$ do not appear at all, as this would require $\mathbb{Q}(\zeta_m)$ to be a subfield of K (because of the Weil pairing [25, Corollary 3.11]), which is impossible. Thus we can ignore the cases $(3, 9), (4, 8)$ and $(6, 6)$, implying that we are left with the cases

$$(m, n) \in \{(1, 11), (1, 14), (1, 15), (2, 10), (2, 12)\}. \quad (1)$$

The number of elliptic curves containing T , for all finite torsion groups T , was determined by Kamienny and the author [8] over all quadratic fields and by the author [19] over all cubic fields. In both cases there were exceptional cases where for a torsion group parameterized by a modular curve of genus 1, there are a few fields over which there is a positive finite number of curves containing T . Note also that in [20] it is proven that there are infinitely many such quartic fields. In this paper, we prove that there are no such curves over a number field of degree d , where d is not divisible by any of $2, 3$

or 5. For $p = 5$, and for the torsion group $T = \mathbb{Z}/11\mathbb{Z}$, we find that there are 3 elliptic curves with torsion T over $\mathbb{Q}(\zeta_{11})^+$ (the maximal real subfield of $\mathbb{Q}(\zeta_{11})$, generated by the element $\zeta_{11} + \zeta_{11}^{-1}$) and either none or infinitely many curves with torsion T over any other quintic number fields.

We state our results in the following two theorems.

Theorem 1. *a) Let d be a positive integer coprime to 6 and K a number field of degree d . If T is one of the following groups*

$$\mathbb{Z}/n\mathbb{Z}, \text{ where } n = 1, \dots, 10, 12, 14, 15,$$

$$\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2n\mathbb{Z} \text{ where } n = 1, \dots, 6, \quad (2)$$

then there are either none or infinitely many elliptic curves over K containing T as a subgroup. If T is any other finite group, $T \neq \mathbb{Z}/11\mathbb{Z}$, then there are only finitely many (maybe 0) elliptic curves containing T as a subgroup.

b) Let d be a positive integer not divisible by 3 nor 4 nor 5 and K a number field of degree d . Then there are either none or infinitely many elliptic curves over K containing $\mathbb{Z}/11\mathbb{Z}$ as a subgroup.

We can summarize our results in a slightly weaker but "nicer" version. The following corollary follows trivially from Theorem 1.

Corollary 2. *Let d be a positive integer not divisible by any of 2, 3 or 5, and let K be a number field of degree d . If T is one of the following groups*

$$\mathbb{Z}/n\mathbb{Z}, \text{ where } n = 1, \dots, 12, 14, 15,$$

$$\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2n\mathbb{Z} \text{ where } n = 1, \dots, 6, \quad (3)$$

then there are either none or infinitely many elliptic curves over K containing T as a subgroup. If T is any other finite group, then there are only finitely many (maybe 0) elliptic curves containing T as a subgroup.

To complete our goal of counting the number of elliptic curves with prescribed torsion over number fields of prime degree, we need to deal with number fields of degree 5.

Theorem 3. *Let K be a number field of degree 5.*

a) If T is one of the following groups

$$\mathbb{Z}/n\mathbb{Z}, \text{ where } n = 1 \dots 10, 12, 14, 15,$$

$$\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2n\mathbb{Z} \text{ where } n = 1 \dots 6, \quad (4)$$

then there are either none or infinitely many elliptic curves over K containing T as a subgroup.

b) There are exactly three elliptic curves with 11-torsion over $\mathbb{Q}(\zeta_{11})^+$. Over any other quintic field there are either none or infinitely many elliptic curves with 11-torsion.

c) If T is any other finite group, then there are only finitely many (maybe 0) elliptic curves over K containing T as a subgroup.

Theorems 1 and 3 combined with the results of [8] for $p = 2$ and [19] for $p = 3$ completely solve the problem of counting elliptic curves containing a prescribed torsion group over number fields of prime degree. Note that the results of [20] suggest that we should expect there to be infinitely many fields F of degree d , where d is divisible by 2, 3 or 5, such that there is a finite positive number of elliptic curves over F with some of the torsion groups from the list (2).

Remark 1.

An elliptic curve over $\mathbb{Q}$ has one of the following 15 groups (see [15] for the proof):

$$\mathbb{Z}/n\mathbb{Z}, \text{ where } n = 1 \dots 10, 12$$

$$\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2n\mathbb{Z} \text{ where } n = 1 \dots 4, \quad (5)$$

For any number field K , there are infinitely many elliptic curves containing any of the groups from (5). All of the groups (5) are parameterized by modular curves of genus 0. All the remaining groups from (2), (3) and (4) are parameterized by a curve of genus 1.

For a given torsion $T = \mathbb{Z}/m\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}$, such that the modular curve $X_1(m, n)$ is of genus 1, and a number field K , if there is a finite positive number of elliptic curves with torsion T over K , then the following two conditions hold.

1. $\text{rank}(X_1(m, n)(K)) = 0$.
2. At least one of the torsion points of $X_1(m, n)(K)$ is not a cusp (note that this implies $|X_1(m, n)(K)|_{\text{tors}} > |X_1(m, n)(\mathbb{Q})|_{\text{tors}}$).

To prove Theorems 1 and 3, we will use division polynomials and Galois representations.

We denote by ψ_n the n -th division polynomial, which satisfies that, for a point P on an elliptic curve in Weierstrass form, $\psi_n(x(P)) = 0$ if and only if $nP = 0$. For a definition and more information on division polynomials see [25]. Note that this implies that the point P will be defined either over the number field F obtained by adjoining a root of ψ_n or over a quadratic extension of F .

Let $E[n]$ denote the n -th division group of E over $\overline{\mathbb{Q}}$ and let $\mathbb{Q}(E[n])$ be the n -th division field of E . The Galois group $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ acts on $E[n]$ and gives rise to an embedding $\phi_n : \text{Gal}(\mathbb{Q}(E[n])/\mathbb{Q}) \hookrightarrow \text{GL}_2(\mathbb{Z}/n\mathbb{Z})$ called a *Galois representation associated to $E[n]$* . Serre's Open Image Theorem [22] tells us that for an elliptic curve without complex multiplication (all of the $X_1(m, n)$ -s that we study do not have complex multiplication) this embedding is surjective for all but finitely many primes. The primes for which this embedding is possibly not surjective can be computed in SAGE [23] with the `non_surjective()` function, which uses the bounds for the non-surjective primes from [1].

We prove Theorems 1 and 3 simultaneously as the proof of both will require us to look at the fields of definition of points of $X_1(m, n)$ whose order is a prime power. Our strategy is to find the fields of prime degree over which $X_1(m, n)$, where (m, n) is a pair from the list (1), has torsion larger than over $\mathbb{Q}$.

Proof of Theorems 1 and 3. Let E be an elliptic curve without complex multiplication.

Let l be an odd prime such that the Galois representation ϕ_l is surjective. First note that the division polynomial ψ_l is irreducible. The field of definition F of a torsion point of order l has to contain the field obtained by adjoining a root of ψ_l to $\mathbb{Q}$, which is a field of degree $(l^2 - 1)/2$. In particular F has to be divisible by 4.

If $E(\mathbb{Q})$ has at least one 2-torsion point, then by [19, Lemma 1], the 2-Sylow subgroup of $E(K)$ is equal to the 2-Sylow subgroup of $E(\mathbb{Q})$. Suppose now $E(\mathbb{Q})[2] = 0$. One can then write $E(\mathbb{Q})$ in short Weierstrass form $y^2 = f(x)$, where $f(x)$ is an irreducible degree 3 polynomial, and conclude that any number field containing a 2-torsion point has to have the field obtained by adjoining a root of f to $\mathbb{Q}$ as a subfield. Thus, any number field of degree not divisible by 3, cannot have any 2-torsion.

Combining these two cases, we see that for any number field K of degree coprime to 6, the 2-Sylow subgroup of $E(K)$ is equal to the 2-Sylow subgroup

of $E(\mathbb{Q})$.

Thus we are left only to deal, for each elliptic curve $X_1(m, n)$, with the odd primes l for which the Galois representation ϕ_l is not surjective. For all the $X_1(m, n)$ -s we study, we list the primes (computed in SAGE) for which the Galois representation ϕ_l is not surjective in the table below.

Modular curve	primes l for which ϕ_l is not surjective
$X_1(11)$	5
$X_1(14)$	2, 3
$X_1(15)$	2
$X_1(2, 10)$	2, 3
$X_1(2, 12)$	2

Table 1.

We start with $X_1(11)$ and the prime 5. The curve elliptic curve $X_1(11)$ has the following Weierstrass model

$$y^2 - y = x^3 - x^2$$

and $X_1(11)(\mathbb{Q}) \simeq \mathbb{Z}/5\mathbb{Z}$ and all the rational torsion points are cusps. Since no number field of odd degree contains $\mathbb{Q}(\zeta_5)$ as a subfield, $X_1(11)(F)[5] \simeq \mathbb{Z}/5\mathbb{Z}$, for all number fields F of odd degree. We now factor the 25-division polynomial of $X_1(11)$ and obtain the factorization

$$\psi_{25} = \psi_5 f_5 g_5 f_{20} g_{20} f_{250},$$

where f_n and g_n are irreducible polynomials of degree n . We need to examine only the fields generated by f_5 and g_5 , as the zeroes of ψ_5 correspond to the 5-torsion points, which are either rational (and thus cusps) or are defined over a field of even degree, and as f_{20} , g_{20} and f_{250} generate fields of even degree.

We compute that f_5 and g_5 generate the same field, $\mathbb{Q}(\zeta_{11})^+$. We compute $X_1(11)(\mathbb{Q}(\zeta_{11})^+)_{tors} \simeq \mathbb{Z}/25\mathbb{Z}$ and $rank(X_1(11)(\mathbb{Q}(\zeta_{11})^+)) = 0$ (via 2-descent). The curve $X_1(11)$ has 10 cusps over $\mathbb{Q}(\zeta_{11})^+$ (see [3, Example 9.3.5]), thus there are 15 non-cuspidal points on $X_1(11)(\mathbb{Q}(\zeta_{11})^+)$. As $\mathbb{Z}/11\mathbb{Z}$ has 10 generators and each point on $X_1(11)(\mathbb{Q}(\zeta_{11})^+)$ corresponds to a pair $(E, \pm P)$, where P is a point of order 11, we see that this implies that there are 3 elliptic curves with 11-torsion over $X_1(11)(\mathbb{Q}(\zeta_{11})^+)$. We also conclude that $\mathbb{Q}(\zeta_{11})^+$ is the only quintic field such that there is a positive finite number of elliptic curves with 11-torsion over it and that if K is a number field of degree not divisible by 2, 3 or 5 (as to not contain $\mathbb{Q}(\zeta_{11})^+$)

then there are either none or infinitely many elliptic curves with 11-torsion over K .

We move on to $X_1(14)$ and the prime 3. The elliptic curve $X_1(14)$ has a Weierstrass model

$$y^2 + xy + y = x^3 - x$$

and $X_1(14)(\mathbb{Q}) \simeq \mathbb{Z}/6\mathbb{Z}$, where all the rational torsion points are cusps. We factor its 9-division polynomial ψ_9 and obtain

$$\psi_9 = \psi_3 f_3 f_6 f_{27},$$

where f_n is an irreducible polynomial of degree n . As in the previous case, the zeroes of ψ_3 do not concern us. From the factorization of ψ_9 , we see that there are no points on $X_1(14)$ of order 9 over any number field of degree not divisible by 3. Thus $X_1(14)$ has no non-rational torsion points over any number field of degree not divisible by 2 or 3.

The case $X_1(2, 10)$ and the prime 3 remain. The elliptic curve $X_1(2, 10)$ has a Weierstrass model

$$y^2 = x^3 + x^2 - x$$

and $X_1(2, 10)(\mathbb{Q}) \simeq \mathbb{Z}/6\mathbb{Z}$, where all the rational torsion points are cusps. We factor its 9-division polynomial ψ_9 and obtain

$$\psi_9 = \psi_3 f_9 f_{27},$$

where f_n is an irreducible polynomial of degree n . Similarly as in the previous case we can conclude that there are no points on $X_1(2, 10)$ of order 9 over any number field of degree not divisible by 9. Thus $X_1(2, 10)$ has no non-rational torsion points over any number field of degree not divisible by 2 or 9.

Combining all the cases we have proven Theorems 1 and 3 □

Remark 2. Let α be the root of the polynomial $x^5 - 18x^4 + 35x^3 - 16x^2 - 2x + 1$ which generates $\mathbb{Q}(\zeta_{11})^+$. The 3 elliptic curves over $\mathbb{Q}(\zeta_{11})^+$ with 11-torsion are

$$\begin{aligned} y^2 + \frac{4\alpha^4 - 73\alpha^3 + 150\alpha^2 - 96\alpha + 27}{11}xy + \frac{3\alpha^4 - 19\alpha^3 + 19\alpha^2 - 6\alpha + 1}{11}y &= \\ &= x^3 + \frac{3\alpha^4 - 19\alpha^3 + 19\alpha^2 - 6\alpha + 1}{11}x^2, \quad (6) \\ y^2 + \frac{2\alpha^4 - 32\alpha^3 + 68\alpha - 8}{11}xy + \frac{-6\alpha^4 + 111\alpha^3 - 261\alpha^2 + 190\alpha - 33}{11}y &= \end{aligned}$$

$$= x^3 + \frac{-6\alpha^4 + 111\alpha^3 - 261\alpha^2 + 190\alpha - 33}{11}x^2 \quad (7)$$

and

$$y^2 + \frac{xy}{11}(45\alpha^4 - 799\alpha^3 + 1379\alpha^2 - 372\alpha - 179) + \frac{y}{11}(372\alpha^4 - 6605\alpha^3 + 11404\alpha^2 - 3157\alpha - 1519) = x^3 + \frac{x^2}{11}(372\alpha^4 - 6605\alpha^3 + 11404\alpha^2 - 3157\alpha - 1519). \quad (8)$$

The curves (6), (7), (8) have j -invariants $-11 \cdot 131^3$, -2^{15} and -11^2 respectively. The curve (7) has complex multiplication by the ring of integers $\mathbb{Q}(\sqrt{-11})$, while the other two curves do not have complex multiplication. The elliptic curves above were constructed using the formulas from [24].

3 Number of elliptic curves with an n -isogeny

As we are studying elliptic curves with an n -isogeny, we are led to the study of the modular curves $X_0(n)$.

If $X_0(n)$ is of genus 0 (when $n \leq 10$, $n = 12, 13, 16, 18$ or 25), then there is already infinitely many elliptic curves with an n -isogeny over $\mathbb{Q}$.

Let S be the set of n -s such that $X_0(n)$ is of genus 1, i.e.

$$S = \{11, 14, 15, 17, 19, 20, 21, 24, 27, 32, 36, 49\}. \quad (9)$$

Note that $|Y_0(n)(\mathbb{Q})|$ is finite for all $n \in S$. The curve $Y_0(n)(\mathbb{Q})$ has 1 point for $n = 11$ and 27, 2 points for $n = 14$ and 17, 3 points for $n = 15$, 4 points for $n = 21$ and 0 points for the remaining genus 1 cases.

As in the previous section, we will be interested in finding the fields K of prime degree for which the elliptic curve $X_0(n)$ has larger torsion than over $\mathbb{Q}$, but still has rank 0.

We state our results in the following theorem.

Theorem 4. *The only pairs (n, K) , where $n \in S$ and K is a number field of prime degree such that $|Y_0(n)(\mathbb{Q})| < |Y_0(n)(K)| < +\infty$ are listed in the table below.*

n	K	$ Y_0(n)(K) $
14	$\mathbb{Q}(\sqrt{-7})$	8
14	$\mathbb{Q}(\sqrt{-3})$	14
15	$\mathbb{Q}(\sqrt{5})$	12
15	$\mathbb{Q}(i)$	12
20	$\mathbb{Q}(i)$	6
21	$\mathbb{Q}(\sqrt{-3})$	12
27	$\mathbb{Q}(\sqrt{-3})$	7
32	$\mathbb{Q}(i)$	4
49	$\mathbb{Q}(\sqrt{-7})$	2

Table 2.

Proof. We first deal with the cases when $X_0(n)$ does not have complex multiplication, i.e. $n \in \{11, 14, 15, 17, 19, 20, 21, 24\}$. As in the proof of Theorems 1 and 3, for each $X_0(n)$, we compute primes l for which the Galois representation ϕ_l is not surjective. We list the obtained results in the table below.

Modular curve	primes l for which ϕ_l is not surjective
$X_0(11)$	5
$X_0(14)$	2, 3
$X_0(15)$	2
$X_0(17)$	2
$X_0(19)$	3
$X_0(20)$	2, 3
$X_0(21)$	2
$X_0(24)$	2

Table 3.

We start by proving that there is no number field K of prime degree such that $|X_0(11)(\mathbb{Q})| < |X_0(11)(K)| < +\infty$. We factor the 5-division polynomial of $X_0(11)$ and obtain that $x^2 + x - 29/5$ is the only factor of prime degree, but $X_0(11)(\mathbb{Q}(\sqrt{5})) = X_0(11)(\mathbb{Q}) \simeq \mathbb{Z}/5\mathbb{Z}$.

The 25-division polynomial $X_0(11)$ has no factors of prime degree, except the ones corresponding to the 5-division polynomial. Thus, we have dealt with $X_0(11)$.

By examining $X_0(14)$ over the number fields generated by the factors of prime degree of the 8-division and 9-division polynomials, we obtain

$$X_0(14)(\mathbb{Q}(\sqrt{-7}))_{tors} \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/6\mathbb{Z} \text{ and } X_0(14)(\mathbb{Q}(\sqrt{-3}))_{tors} \simeq \mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/6\mathbb{Z}$$

and $X_0(14)(K)_{tors} = X_0(14)(\mathbb{Q})_{tors}$ for all other fields K of prime degree. We compute that the rank of $X_0(14)$ over both $\mathbb{Q}(\sqrt{-3})$ and $\mathbb{Q}(\sqrt{-7})$ is 0. Thus $Y_0(14)(\mathbb{Q}(\sqrt{-7}))$ has 8 points ($|X_0(14)(\mathbb{Q}(\sqrt{-7}))|$ minus the 4 rational cusps) and $Y_0(14)(\mathbb{Q}(\sqrt{-3}))$ has 14 points.

By examining $X_0(15)$ over the number fields generated by the factors of prime degree of the 8-division polynomial, we obtain

$$X_0(15)(\mathbb{Q}(i))_{tors} \simeq \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z} \text{ and } X_0(15)(\mathbb{Q}(\sqrt{5}))_{tors} \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/8\mathbb{Z}$$

and $X_0(15)(K)_{tors} = X_0(15)(\mathbb{Q})_{tors}$ for all other fields K of prime degree. We compute that the rank of $X_0(15)$ over both $\mathbb{Q}(i)$ and $\mathbb{Q}(\sqrt{5})$ is 0. Thus, by removing the 4 rational cusps of $X_0(15)$, we obtain that $Y_0(15)(\mathbb{Q}(i))$ and $Y_0(15)(\mathbb{Q}(\sqrt{5}))$ have 12 points.

We factor the 8-division polynomial of $X_0(17)$ and obtain that the only number field K of prime degree such that $X_0(17)$ has torsion points defined over K , but not over $\mathbb{Q}$, is $K = \mathbb{Q}(i)$. But we compute that the rank of $X_0(17)(\mathbb{Q}(i))$ is 1, and hence there is infinitely many elliptic curves with a 17-isogeny over $\mathbb{Q}(i)$.

We factor the 9-division polynomial of $X_0(19)$ and obtain that the only number field K of prime degree such that $X_0(19)$ has torsion points defined over K , but not over $\mathbb{Q}$, is $K = \mathbb{Q}(\sqrt{-3})$. But, as in the previous case, the rank of $X_0(19)(\mathbb{Q}(\sqrt{-3}))$ is 1, and hence there is infinitely many elliptic curves with a 19-isogeny over $\mathbb{Q}(\sqrt{-3})$.

By examining $X_0(20)$ over the number fields generated by the factors of prime degree of the 8-division and 9-division polynomials, we obtain

$$X_0(20)(\mathbb{Q}(i))_{tors} \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/6\mathbb{Z}$$

and $X_0(20)(K)_{tors} = X_0(20)(\mathbb{Q})_{tors}$ for all other fields K of prime degree. We compute that the rank of $X_0(20)$ over $\mathbb{Q}(i)$ is 0, and hence $Y_0(20)(\mathbb{Q}(i))$ has 6 points (we subtract the 6 rational cusps of $X_0(20)$).

In a similar manner we obtain that the only field of prime degree K such that $X_0(21)$ has torsion points defined over K , but not over $\mathbb{Q}$, is $K = \mathbb{Q}(\sqrt{-3})$, and that the rank of $X_0(21)(K)$ is 0. Hence $Y_0(21)(\mathbb{Q}(\sqrt{-3}))$ has 12 points (we subtract the 4 rational cusps of $X_0(21)$).

By examining $X_0(24)$ over the number fields generated by the factors of prime degree of the 8-division, we obtain that $X_0(24)(K)_{tors} = X_0(24)(\mathbb{Q})_{tors}$ for all number fields of prime degree.

For the remaining cases $n \in S$, $X_0(n)$ is a curve with complex multiplication, so we cannot apply the same methods as before. Instead we use

the results of [4] which give a good description of the behavior of the torsion of an elliptic curve with complex multiplication defined over $\mathbb{Q}$ upon extensions.

To find all the number fields K of prime degree such that $|X_0(32)(\mathbb{Q})| < |X_0(32)(K)| < +\infty$, by [4, Theorem 2], we just need to check the 8-division polynomial of $X_0(32)$ and check what is $X_0(32)(\mathbb{Q}(i))$. We obtain that the only field K with the desired property is $K = \mathbb{Q}(i)$, and

$$X_0(32)(\mathbb{Q}(i))_{tors} \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}.$$

The rank of $X_0(32)(\mathbb{Q}(i))$ is 0, and hence we obtain that $Y_0(32)(\mathbb{Q}(i))$ has 4 points.

Similarly, for $X_0(36)$, by [4, Theorem 2], we need to check the 9-division polynomial and $X_0(36)(\mathbb{Q}(\sqrt{-3}))$. We obtain

$$X_0(36)(\mathbb{Q}(\sqrt{-3}))_{tors} \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/6\mathbb{Z}$$

and $X_0(36)(K)_{tors} = X_0(36)(\mathbb{Q})_{tors}$ for all other fields K of prime degree. The rank of $X_0(36)(\mathbb{Q}(\sqrt{-3}))$ is 0, and hence $Y_0(36)(\mathbb{Q}(\sqrt{-3}))$ has 6 points.

Finally, for $X_0(49)$, by [4, Theorem 2], we need to check the 4-division and 7-division polynomials and $X_0(49)(\mathbb{Q}(\sqrt{-7}))$. We obtain

$$X_0(49)(\mathbb{Q}(\sqrt{-7}))_{tors} \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$$

and $X_0(49)(K)_{tors} = X_0(49)(\mathbb{Q})_{tors}$ for all other fields K of prime degree. The rank of $X_0(49)(\mathbb{Q}(\sqrt{-7}))$ is 0, and hence $Y_0(49)(\mathbb{Q}(\sqrt{-7}))$ has 2 points. $\square$

4 Curves with an n -isogeny having a twist with n -torsion

An elliptic curve E/K with n -torsion has an n -isogeny and hence so do all twists of E .

In this section we study when is the converse true:

Problem 1. *For which pairs (n, K) , where $n > 2$ is a integer and K a number field, does every elliptic curve E/K with an n -isogeny have a quadratic twist with an n -torsion point?*

We exclude the case $n = 2$, since an elliptic curve has a 2-isogeny if and only if it has 2-torsion.

We solve the problem completely for all the pairs (n, K) , where n is an integer such that there exists at least one elliptic curve with an n -isogeny over $\mathbb{Q}$, and where $K = \mathbb{Q}$ or K is a number field of prime degree. The restriction on n stems from the fact that already over quadratic fields, one does not know which are the possible degrees of isogenies.

In the table below, for each such n , we list the genus g of $X_0(n)$, and the number m of $\overline{\mathbb{Q}}$ -isomorphism classes of elliptic curves with an n -isogeny in the table below.

n	g	m	n	g	m	n	g	m
≤ 10	0	∞	11	1	3	27	1	1
12	0	∞	14	1	2	37	2	2
13	0	∞	15	1	4	43	3	1
16	0	∞	17	1	2	67	5	1
18	0	∞	19	1	1	163	13	1
25	0	∞	21	1	4			

Table 4.

That this table is complete was proven by Mazur [16] (considering only prime n -s) and by Kenku [9, 10, 11, 12] (by ruling out the remaining composite cases).

Denote by T the set of values n appearing in Table 4, i.e. the set of values such that there exists an n -isogeny over $\mathbb{Q}$.

Let $\phi : E \rightarrow E'$ be an isogeny of degree n over K . Then $C = \text{Ker } \phi \simeq \mathbb{Z}/n\mathbb{Z}$ is $\text{Gal}(\overline{K}/K)$ -invariant, although not all the points of $\text{Ker } \phi$ need be defined over K . The group C is called an n -cycle of E or a cyclic subgroup of E . We will say that C is defined over a extension F/K if all the points of C are defined over F .

We start with the case $K = \mathbb{Q}$. We believe that the results of the following proposition should be well known, but we were unable to find them anywhere in the literature.

In the proofs, we will use particular elliptic curves and we will list them as they appear in Cremona's tables [2] instead of writing down equations for them.

- Proposition 5.** *a) Let $n = 3, 4$ or 6 and let $E/\mathbb{Q}$ be an elliptic curve with an n -isogeny. Then there exists a twist $E^{(d)}$ of E such that $E^{(d)}(\mathbb{Q})$ has n -torsion.*
- b) Let $n \neq 2, 3, 4$ or 6 and $n \in T$. Then there exists an elliptic curve with an n -isogeny but no quadratic twist with n -torsion over $\mathbb{Q}$.*

Proof. **a)**

Let $n = 3, 4$ or 6 and let E be an elliptic curve with an n -isogeny but no n -torsion over $\mathbb{Q}$. Let C be the corresponding cyclic subgroup of E ; $\tau \in \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ acts on C either as the identity or by permuting the two generators of C . Let $\sigma \in \text{Aut } C$ be the automorphism that permutes the 2 generators of C and let K be the fixed field of σ . As σ is of degree 2, K is a quadratic field, $K = \mathbb{Q}(\sqrt{d})$. Thus $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{d}))$ fixes every element of C , and hence C is defined over $\mathbb{Q}(\sqrt{d})$, implying that $E(\mathbb{Q}(\sqrt{d}))$ has n -torsion.

To deal with the cases $n = 3, 6$ recall that for an odd l ,

$$E(\mathbb{Q}(\sqrt{d}))[l] = E(\mathbb{Q})[l] \oplus E^{(d)}(\mathbb{Q})[l]. \quad (10)$$

Thus we conclude that $E^{(d)}(\mathbb{Q})$ has a 3-torsion point and thus n -torsion.

For the case $n = 4$, let P be a generator of C . Note that $\sigma(P) = 3P = -P$. Thus P is of the form $P = (x, y\sqrt{d})$, where $x, y \in \mathbb{Q}$, $d \in \mathbb{Q}^*/(\mathbb{Q}^*)^2$. This implies $P \in E^{(d)}(\mathbb{Q})$.

b)

For $n = 11$ and $n > 12$ the statement follows trivially from the fact that there are no elliptic curves with n -torsion over $\mathbb{Q}$. We deal with the cases $n = 5, 7, 8, 9, 10, 12$ by giving an explicit example of a curve with an n -isogeny but no twist with n -torsion.

Let $n = 10$ and E_{10} be the curve 870I3 from [2]. If E_{10} had a twist $E_{10}^{(d)}$ such that $E_{10}^{(d)}(\mathbb{Q})$ has 10-torsion, then $E_{10}(\mathbb{Q}(\sqrt{d})) \simeq E_{10}^{(d)}(\mathbb{Q}(\sqrt{d}))$ would have to have 10-torsion. But by factoring the 5-division polynomial of E_{10} , one can see that there is no such quadratic field (the 5-division polynomial has one quadratic factor, but E_{10} has no 5-torsion points over the fields generated by this factor). This also deals with the case $n = 5$.

In exactly the same way one can show that the curves E_n , where E_7 is 26B2, E_8 is 714G6, E_9 is 714I3 and E_{12} is 90C4, have an n -isogeny but no n -torsion points over any quadratic field. $\square$

We move on to the case when K is an extension $K/\mathbb{Q}$ of prime degree. We first give an easy proposition that will eliminate certain values of $n \in T$ for all number fields K (not just the ones with prime degree).

Proposition 6. *Let $n = 13, 16, 18$ or 25 . Then over any number field K there exists an elliptic curve with an n -isogeny, but with no twist with a point of order n .*

Proof. Over $\mathbb{Q}$ (and hence also over any number field K), there is infinitely many elliptic curves with an n -isogeny. But $X_1(n)$ is of genus ≥ 2 and

hence (by Faltings' theorem) has only finitely many points over K . Thus only finitely many curves can have a twist with n -torsion. $\square$

Now we deal (over number fields of prime degree) with the remaining $n \in T$ having the property that there are infinitely many curves with an n -isogeny over $\mathbb{Q}$. Parts of the proofs will require tedious but elementary and easily verifiable computations involving polynomials, so we will leave out some of the details.

Proposition 7. *Let K be a number field of prime degree.*

- a) *Let $n = 3, 4$ or 6 and let E/K be an elliptic curve with an n -isogeny. Then there exists a twist $E^{(d)}$ of E such that $E^{(d)}(K)$ has a point of order n .*
- b) *Let $n = 5, 7, 8, 9, 10$ or 12 . Then there exists an elliptic curve E/K with an n -isogeny but no quadratic twist with point of order n over K .*

Proof. The proof of a) is exactly the same as the proof of Proposition 5 a), except for the change of the base field.

We prove b) by contradiction. Let $n = 5, 7, 8, 9, 10$ or 12 and suppose that K is a number field of prime degree such that every elliptic curve with an n -isogeny has a twist with n -torsion over K . Let $E/\mathbb{Q}$ be an elliptic curve with an n -isogeny, but with no twists with n -torsion over $\mathbb{Q}$ (such a curve exists by Proposition 5 b)). This implies that the cyclic subgroup C of order n is defined over some quadratic extension of K . Thus K is a number field such that the fixed field F of C is a extension of K such that $[F : K] \mid 2$. As $|\text{Aut } C| = 4$, for $n = 5, 8, 10, 12$ and $|\text{Aut } C| = 6$ for $n = 7, 9$, we conclude that K has to be a quadratic field if $n = 5, 8, 10$ or 12 and a cubic field if $n = 7, 9$.

We start with $n = 10$. Let E_{10} be the curve 870I3 and

$$E'_{10} : y^2 = x^3 + (768\sqrt{5} - 960)x + (-14336\sqrt{5} + 21504).$$

The field of definition of the 10-cycle of E_{10} is $\mathbb{Q}(\zeta_5)$, and one can check that $\mathbb{Q}(\sqrt{5})$ is the only field of prime degree over which E_{10} has a twist with 10-torsion. On the other hand, E'_{10} has a 10-cycle (which is defined over a quartic extension of $\mathbb{Q}(\sqrt{5})$), and by looking at the 5-division polynomial of E'_{10} , one can see that E'_{10} has no twist over $\mathbb{Q}(\sqrt{5})$ with 5-torsion. Thus, there does not exist a field of prime degree such that every elliptic curve with a 10-cycle has a twist with 10-torsion. This also deals with the case $n = 5$.

For $n = 7$, let E_7 be the curve 26B2 and let E'_7 be the curve 162B2. One can check that the intersection of the fields over which the 7-cycles of E_7 and E'_7 are defined is $\mathbb{Q}$. Hence, over no number field of prime degree will both E_7 and E'_7 have a twist with 7-torsion.

For the case $n = 8$ let E_8 be 714G6 and E'_8 be 45A8. We want to prove that there do not exist quartic fields K_1 and K_2 such that $E_8(K_1)$ and $E'_8(K_2)$ have a point of order 8 and the intersection of K_1 and K_2 is a quadratic field. Suppose the opposite, that such fields K_1 and K_2 exist. By examining the 8-division polynomial of E_8 , we see that K_1 has to have $\mathbb{Q}(\sqrt{3})$ as a subfield. Now we factor the 8-division polynomial of E'_8 over $\mathbb{Q}(\sqrt{3})$ and obtain that E'_8 does not have a point of order 8 over any quadratic extension of $\mathbb{Q}(\sqrt{3})$. Thus there exists no number field K of prime degree such that both E_8 and E'_8 have a twist with a point of order 8 over K .

For the case $n = 9$, let E_9 be 714I3 and let E'_9 be 91B3. The only cubic field over which E_9 has a twist with a point of order 9 is the field K obtained by adjoining a root of $x^3 + 39x^2 - 130x - 13793/3$ to $\mathbb{Q}$. But we check, by factoring the 9-division polynomial of E'_9 that E'_9 has no points of order 9 over any quadratic extension of K .

We are left with the case $n = 12$. Let E_{12} be 90C4 and let E'_{12} be 150C4. We first compute the quartic field K_1 over which E_{12} has a point of order 12. By factoring the 3-division polynomial, we see that K_1 has to contain $\sqrt{-3}$. In a similar way, by factoring the 4-division polynomial, we see that K_1 has to contain $\sqrt{-6}$. Thus $K_1 = \mathbb{Q}(\sqrt{2}, \sqrt{-3})$. In a similar way we compute the quartic field K_2 over which E'_{12} has a point of order 12. We factor the 4-division polynomial and obtain that K_2 has to contain $\sqrt{-10}$, and by factoring the 3-division polynomial we obtain that K_2 has to contain $\sqrt{5}$. As $K_1 \cap K_2 = \mathbb{Q}$, there is no number field K of prime degree such that both E_{12} and E'_{12} have twists over K with a point of order 12. $\square$

Proposition 8. *Let K be a number field of prime degree and $n = 17, 19, 21, 27, 37, 43, 67$ or 163 . Then there exists an elliptic curve E/K with an n -isogeny but no quadratic twist with point of order n over K .*

Proof. We prove the theorem, case by case, eliminating each case by contradiction. Suppose there exists a number field K of prime degree such that every elliptic curve with an n -isogeny has a twist with a point of order n over K .

Let $n = 17$. We conclude that K must be either the field over which the 17-cycle is defined or a quadratic subfield of that field. The 17-cycle is defined over a field of degree dividing $|(\mathbb{Z}/17\mathbb{Z})^*| = 16$, so we conclude that

K has to be a quadratic field. But by [7], there are no elliptic curves with 17-torsion over any quadratic field.

For $n = 19, 37, 163$, by a similar argument as above we conclude that K has to be either a quadratic or cubic field. But by [7] and [21], there are no n -torsion points on quadratic and cubic fields, respectively.

For $n = 27$, we can again in the same way conclude that K has to be either a quadratic or cubic field, but now the nonexistence of elliptic curves with a 27-torsion point is proved for quadratic fields in [13] and for cubic fields in [17].

For $n = 43$ and 67 , let E_n be the unique (as usual, up to $\overline{\mathbb{Q}}$ -isomorphism) rational elliptic curve with complex multiplication by $\mathbb{Q}(\sqrt{-n})$. It is well known that E_n is the only curve with an n -isogeny. We see that for $n = 43$, the degree of K has to divide 42, and for $n = 67$, the degree of K has to divide 66. Again, from [7] and [21], one sees that there are no points of order n over quadratic or cubic field. Thus, for $n = 43$, the degree of K is 7, and for $n = 67$, the degree is 11. But for E or a twist $E^{(d)}$ of E over K to have an n -torsion point, E has to have a torsion point over a quadratic extension of K . But from [4, Lemma 4], we see that the smallest factor of the n -division polynomial of E_n is of degree $(n-1)/2$, making it impossible for E_n to have a point of order n over a quadratic extension of K .

We are left with the case $n = 21$. There are 4 curves over $\mathbb{Q}$ with a 21-isogeny, all in the same isogeny class. These are the curves in the 162C isogeny class. The degree of K has to divide $|(\mathbb{Z}/n\mathbb{Z})^*| = 12$, so K is a quadratic or cubic field. We can eliminate the possibility of K being quadratic by [14]. We factor the 7-division polynomials of the curve 162C1 and obtain that the only cubic field over which this curve has a twist with 7-torsion is generated by a root of the polynomial $x^3 - 48x^2 - 960x + 137216/7$. Denote this field by K_1 . On the other hand, the only cubic field K_2 over which 162C2 has a twist with 7-torsion is generated by a root of the polynomial $x^3 + 6x^2 - 15x - 73$. One easily checks $K_1 \cap K_2 = \mathbb{Q}$, concluding that there exists no field over which both 162C1 and 162C2 have a twist with a point of order 21.

□

Proposition 9. *Let K be a number field of prime degree. Then there exists an elliptic curve E/K with an 15-isogeny but no quadratic twist with point of order 15 over K .*

Proof. Suppose there exists a number field K of prime degree such that every elliptic curve with a 15-isogeny has a point of order 15 over K . Then

over this field K , each of the four curves with a rational 15-isogeny also has a twist with 15-torsion over K . The 4 curves with 15-isogenies are the curves in the 50A isogeny class. One can check by factoring their 5-division polynomial that the only field of prime degree over which any (and in fact all) of them have a twist with 5-torsion is $\mathbb{Q}(\sqrt{5})$. But by [8] there is only one curve with 15-torsion over $\mathbb{Q}(\sqrt{5})$, with j -invariant $-121945/32$. Thus, of the 4 rational curves with a 15-isogeny, only 50A3 has a twist with 15-torsion over $\mathbb{Q}(\sqrt{5})$. $\square$

Note that in the previous proposition, although the 4 rational curves with 15-isogenies all have a twist with 5-torsion and all have a twist with 3-torsion, only 50A3 has a twist which has both 5-torsion and 3-torsion.

Proposition 10. *Over the field $\mathbb{Q}(\zeta_{11})^+$, every elliptic curve with a 11-isogeny has a twist with 11-torsion. Over any other number field K of prime degree, there exists an elliptic curve with a 11-isogeny, but no twist with 11-torsion.*

Proof. From Theorem 3 b), we see that there are exactly 3 elliptic curves with 11-torsion over $\mathbb{Q}(\zeta_{11})^+$. We compute $X_0(11)(\mathbb{Q}(\zeta_{11})^+) = X_0(11)(\mathbb{Q})$, and as there are only, up to $\overline{\mathbb{Q}}$ -isomorphism, 3 curves with 11-isogeny over $\mathbb{Q}$, we conclude that there are only 3 curves with a 11-isogeny over $\mathbb{Q}(\zeta_{11})^+$. Thus, every elliptic curve with a 11-isogeny over $\mathbb{Q}(\zeta_{11})^+$ is a twist of one of the curves given in (6), (7) or (8).

Suppose now that there exists another number field $K \neq \mathbb{Q}(\zeta_{11})^+$ with the property from above. This would imply that the curve 121A1 has a twist with 11-torsion over K . But the 11-division polynomial of 121A1 factors into polynomials of degree 5 and 55, where the field generated by the degree 5 polynomial is $\mathbb{Q}(\zeta_{11})^+$. It follows that $\mathbb{Q}(\zeta_{11})^+$ is the only field of prime degree over which 121A1 has a twist with 11-torsion. $\square$

Proposition 11. *Over the field $\mathbb{Q}(\zeta_7)^+$, every elliptic curve with a 14-isogeny has a twist with 14-torsion. Over any other number field K of prime degree, there exists an elliptic curve with a 14-isogeny, but no twist with 14-torsion.*

Proof. From [19, Theorem 12 b)], we see that there are exactly 2 curves with 14-torsion over $\mathbb{Q}(\zeta_7)^+$. We compute $X_0(14)(\mathbb{Q}(\zeta_7)^+) = X_0(14)(\mathbb{Q})$, and thus we conclude that, as over $\mathbb{Q}$, there are only 2 curves with a 14-isogeny over $\mathbb{Q}(\zeta_7)^+$, implying that every curve with a 14-isogeny has a twist with 14-torsion over $\mathbb{Q}(\zeta_7)^+$.

Suppose now that there exists another number field $K \neq \mathbb{Q}(\zeta_7)^+$ with the property from above. This would imply that the curve 49A1 also has a twist with 11-torsion over K . But the 7-division polynomial factors as the product of polynomials of degree 3 and 21, where the cubic polynomial generates $\mathbb{Q}(\zeta_7)^+$. It follows that $\mathbb{Q}(\zeta_7)^+$ is the only field of prime degree over which 49A1 has a twist with 7-torsion. $\square$
